Problem Set 1

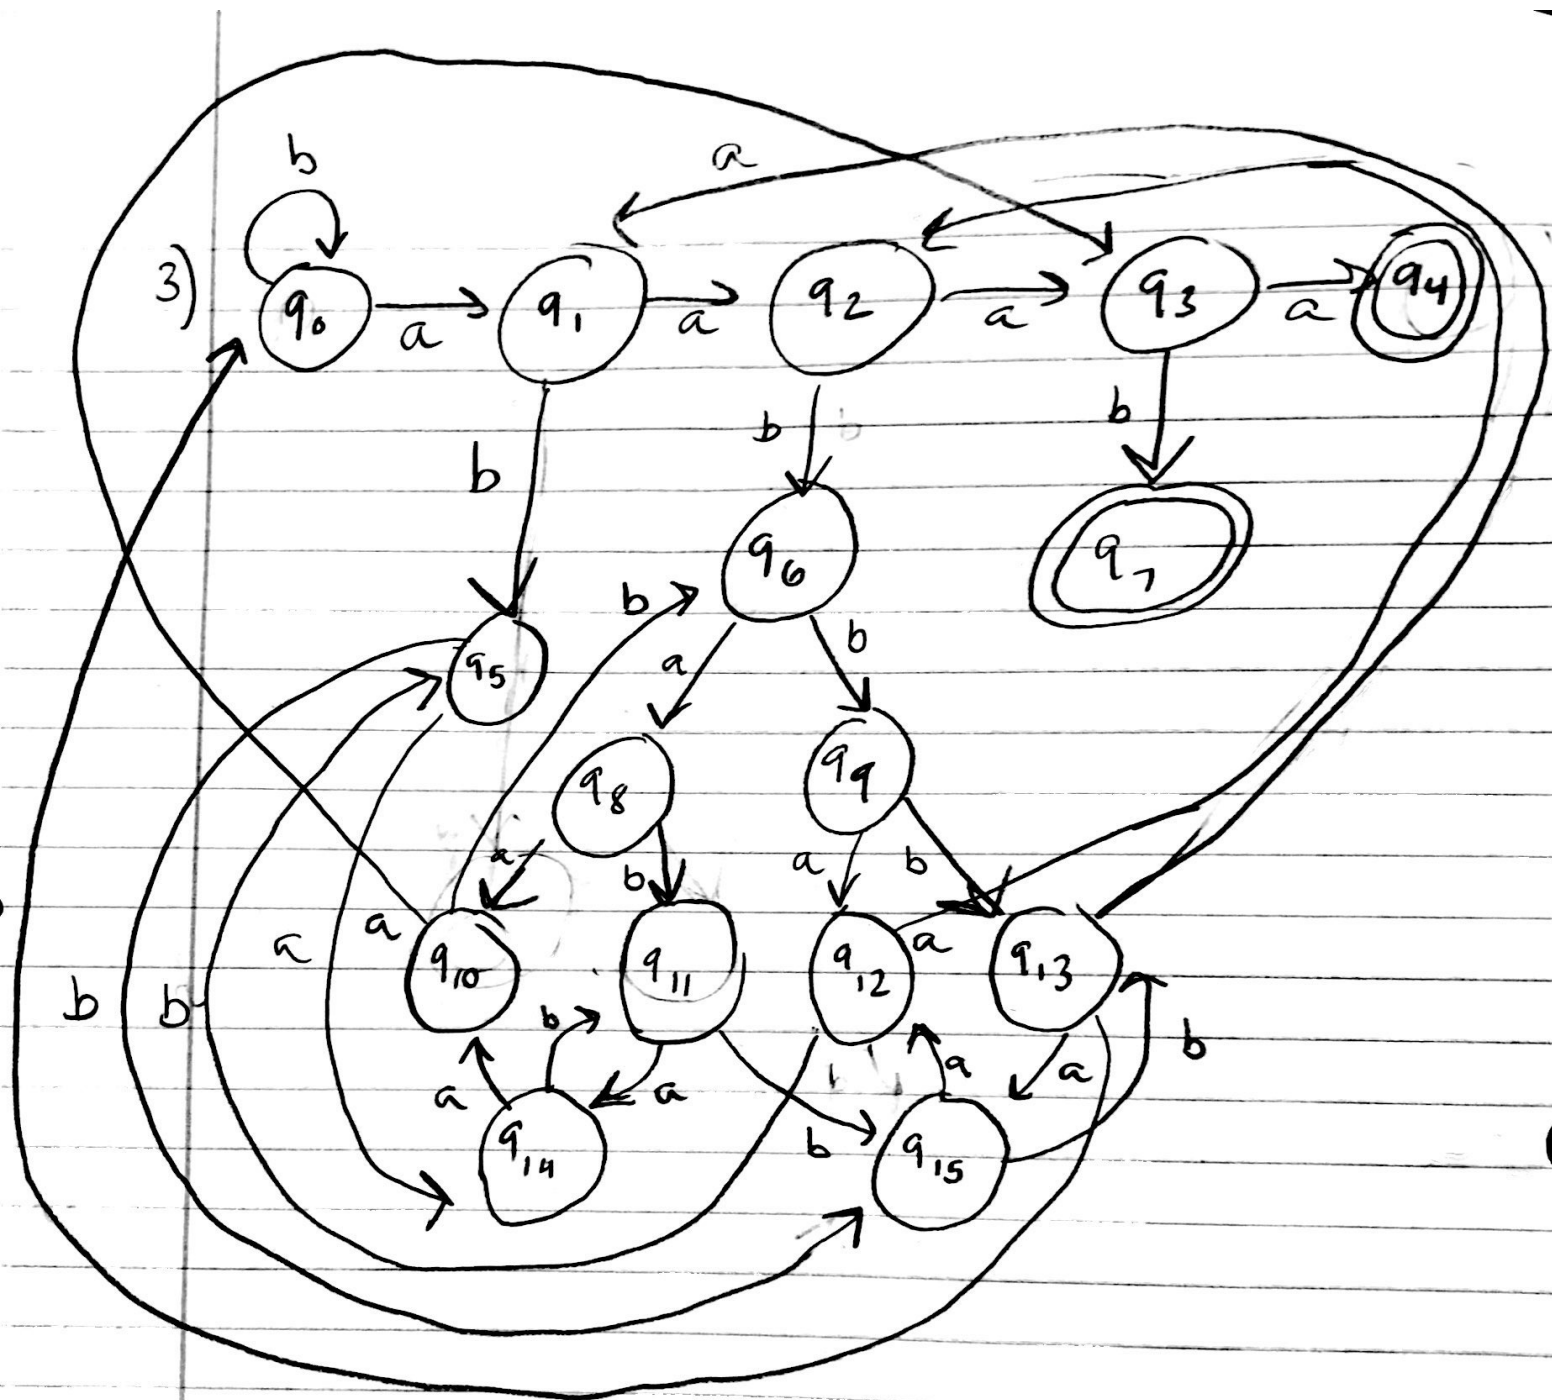

Problem 1:

1)

2)

2) The change must take place in the transition function δ .

We define the function as:

$$\begin{aligned}\delta((r_1, r_2), a) &= \delta(r_1, a), \delta(r_2, a) \text{ if } a \in E_1 \text{ and } a \in E_2 \\ &= (q_1, \delta(r_2, a)) \text{ if } a \in E_2 \text{ and } a \notin E_1 \\ &= (\delta(r_1, a), q_2) \text{ if } a \in E_1 \text{ and } a \notin E_2\end{aligned}$$

remainders: 0 (rem) 1 (rem) 2 (rem)

2. D_k is regular, for every $k \geq 1$ because, by definition, a regular language uses an FSA with Finite States and would not require any memory. Using our pre-existing knowledge of how ~~languages work~~ languages D_2 and D_3 work and that D_2 has two states and D_3 has three states, we can assume that for a finite k , D_k will always have k states, representing the remainders from 0 to $k-1$. As long as k is finite, $k-1$ will be finite, making D_k a regular language.
